LETTER OF TRANSMITTAL.

UNITED STATES DEPARTMENT OF AGRICULTURE, OFFICE OF EXPERIMENT STATIONS, Washington, D. C., June 15, 1896.

SIR: I have the honor to transmit herewith a report on the food supply and consumption in Missouri, made in 1895, by H. B. Gibson, professor of chemistry of the University of Missouri, S. Calvert, and D. W. May. Two dietary studies of a students' club at the University of Missouri and an investigation of the relative bread and meat consumption in families in the State are included in this report. These investigations constitute a part of the inquiries made with aid of the funds appropriated by Congress "to enable the Secretary of Agriculture to investigate and report upon the nutritive value of the various articles and commodities used for human food." They were conducted under the immediate supervision of Prof. W. O. Atwater, special agent in charge of nutrition investigations, in accordance with instructions given by the Director of this Office.

In carrying out the provisions of the act above cited, representative localities have been selected in different parts of the country in order that definite information regarding the food supply and consumption of people living under different conditions might be obtained. The University of Missouri, at Columbia, Mo., offered many facilities for dietary work. It has well-equipped laboratories, and the department of chemistry was under the direction of Professor Gibson, one of the best authorities on dietary work in America. It was the original intention to make a somewhat extended series of investigations, but the work which was begun by Professor Gibson was interrupted by his untimely death in October, 1895. Comments on these investigations made by Professor Atwater and Mr. Woods, and appended to Professor Gibson's report herewith, indicate the value of the Missouri dictary investigations when taken in connection with those carried on elsewhere.

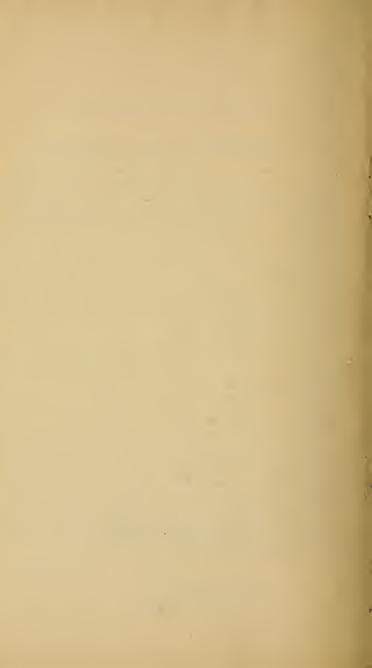

Professor Gibson's report and the accompanying comments by the special agents of this Department are respectfully submitted, with the recommendation that they be published as Bulletin No. 31 of this Office.

Respectfully,

A. C. TRUE,

Director.

Hon. J. Sterling Morton, Secretary of Agriculture.

INVESTIGATIONS CONCERNING FOOD SUPPLY AND CONSUMPTION IN MISSOURI IN 1895.

This investigation has been prosecuted in two directions, namely, (1) an inquiry regarding the bread and meat consumption in the State, and (2) the studies of two dietaries of a students' boarding club at the State university.

PLAN OF INVESTIGATIONS.

The methods followed in the two dietaries described in this report are essentially those explained by Professor Atwater in a previous publication of this Office. The waste, however, was treated in a different way, which is described in detail. The methods used in analysis are those described in the report of the Connecticut Storrs Station for 1891, pp. 47-49, and in Bulletin No. 29 of this Office, p. 8.

BREAD AND MEAT CONSUMPTION.

The university community furnishes an excellent field for the collection of approximate statistics regarding the dietary practices which prevail throughout the State. The students represent almost every county in the State, and are drawn from families in all the ordinary walks of life. Information furnished by them as to the kinds and approximate quantities of bread and meat used in their homes, while doubtless not accurate in comparison with, for instance, the statistical results of the study of a dietary, compares favorably with the quality of the average statistical information. With a view to the collection of information of this character, a circular, of which the following list of questions formed the essential feature, was placed in the hands of the students of the university:

GENERAL STATISTICS.

Home residence. Town, ----. County, ----.

Occupation.—Please underscore the occupation of the head of your family: Farmer. Mechanic. Business. Professional.

Family.—Number of persons over 18 years, ——. Number of persons 12 to 18 years, ——. Number of persons under 12 years, ——.

SPECIAL STATISTICS.

Bread.—Please state the approximate percentages of the following kinds of bread used in your home: Biscuit, — per cent: light bread, — per cent; corn bread. — per cent.

Meat.—Please state the approximate percentages of the following kinds of meat used in your home: Beef, — per cent; veal, — per cent; pork, — per cent; mutton, — per cent; poultry, — per cent; game, — per cent; fish, — per cent.

Two hundred and eighty-two replies, representing as many families, living in 74 of the 114 counties of the State, were received. These statistics are given in a condensed form in Table 1. The proportions of the various kinds of bread and meat used at the college boarding club are also included in the table, the quantities of biscuit and combread being estimated from the amounts of flour and corn meal which were consumed during the dietary tests. All the raised bread used at the club was purchased at a local bakery.

The figures in the table express percentages and not amounts. Those for bread show the percentage which each kind is estimated to make of the total bread used. The same is true with the meat. That is to say, when the reports from the farmers' families were classified and their statements averaged, it appeared that in 142 families, living in 59 counties, the average number of persons per family was 6.4. Of every 100 pounds of "bread" used by these families 53.7 pounds were in the form of biscuit, 30.7 pounds were raised bread, and 15.6 pounds corn bread. Of the total weight of meat 56.9 per cent was pork, 20.9 beef, and 12.9 poultry, the remainder consisting of mutton, veal, fish, and game.

Table 1 .- Approximate bread and meat consumption of families in Missouri.

	Fam	ilies.	Ğ.	Kind	ls of b	read.			Kin	ds of n	neat.

The contrast between the food consumption of the farmers' families (country population) and those of mechanics, business and professional men (largely town population) is well defined, and in some respects even striking. Especially is this true of the meats consumed. The farmer does not have easy access to the butcher's shops, and furthermore has no conveniences for keeping fresh beef. He therefore lives largely on pork and poultry, the fermer being more palatable when preserved than when fresh, and the latter always at hand.

THE DIETARY STUDIES.

The university boarding club is specially adapted to a dietary study. This club, which has a membership of approximately 100, is conducted in essentially the same manner as the numerous boarding clubs which form such a prominent feature of American college communities. Its members, with few if any exceptions, are Missourians, coming from families engaged in the ordinary vocations and living in all portions of the State. These young men live in a thoroughly substantial although modest fashion, their table being, in so far as practicable, copied after the dietary practices of their own homes. The extent to which they succeed in this may be seen from Table 1. The percentages of biscuit, raised bread, and corn bread do not differ essentially from those prevalent in the State at large; that of the beef is noticeably higher. This is due largely to two causes, namely, an opportunity for the storage of fresh meat, which is of course wanting in rural communities, and perhaps more especially to the fact that the club buys its beef by the quarter during a considerable portion of the year.

The details of the dietaries will be found beyond (Tables 6, 7, 8, 9, 10, and 11). The preliminary test (No. 94)¹ covered a period of six consecutive days, and the final test (No. 95) a period of seven consecutive days. The amount of nutrients purchased, wasted, and eaten per man per day in each test and the average of the two are shown in the

following table:

Table 2.-Nutrients purchased, wasted, and eaten per man per day.

	Protein.	Fat.	Carbohy- drates.	Fuel value.	Nutritive ratio.
Purchased:	Grams.	Grams.	Grams.	Calories.	
No. 94	107	169	458	3, 885	
No. 95	107	183	443		
Average		176	450		
Wasted:			100	0,020	
No. 94	11	14	41	350	
No. 95		18	39		
Average		16	40		
Eaten:	11	10	*0	000	
No. 94	96	155	417	3, 540	1:8.0
No.95		165	404	3, 585	1:8.0
Average.		160	410	3, 560	1:8.

These dietaries are striking in point of their comparatively high potential energy and wide nutritive ratio, due to the relatively large proportions of fats and carbohydrates. The protein consumed (95 grams) is slightly below the average, and furthermore 40 per cent of the protein is of vegetable origin, principally from bread. Inasmuch as the digestibility of the vegetable protein is slightly less than that of the animal protein, the actual metabolism of the nitrogen compounds could hardly have exceeded 90 grams. This possible shortage seems

¹The numbers of the dietary studies are laboratory numbers used in the investigations of which this study forms a part.

to have been covered by an increased consumption of fats, the average amount being 161 grams. This substitution can, however, scarcely be regarded as detrimental, as it does not entail an undesirable excess of the carbohydrates, which is usually the most noticeable defect in dietaries with so wide a nutritive ratio.

The protein compounds form 14.4 per cent of the weight of the total nutrients, and their energy amounts to 11 per cent of the total energy.

The method employed in handling the table and kitchen wastes deserves special attention. The wastes were kept in three distinct portions, namely, (1) meats and other animal food materials; (2) bread of all descriptions, and (3) vegetables. No attempt was made to dry this material, but at intervals of a few days, the interval depending on the rapidity of the accumulation and the weather, each portion was treated as follows:

- 1. Meat, etc.—All bone was removed and the edible portion was chopped, weighed, and sampled. This sample was then prepared for analysis in the ordinary manner.
- 2. Bread.—The various kinds of bread were separated, weighed, sampled, and analyzed in the usual way.
- 3. Vegetables.—This portion of the waste was thoroughly mixed, weighed, and sampled and the sample prepared for analysis in the same way as the meats. Each sample of meat and vegetable waste was analyzed separately, although "composite samples" might have been made.

This method has two decided advantages—first, a great saving of labor and fuel, and second, the possibility of an actual division of the nutrients according to their respective sources, namely, animal foods, bread and breadstuffs, and vegetables.

DESCRIPTION OF FOOD MATERIALS ANALYZED.

In connection with the dietary studies the following analyses were made:

Beef.—The local market was considerably affected by the unusually high prices which prevailed at the time when these dietary studies were made (May, 1895). Much of the beef offered for sale had been raised in the immediate vicinity, and at that season was very young, watery, and often immature as well; high prices elsewhere had forced it upon the market before it was in the proper condition.

With the exception of the samples of porterhouse steak (86) and rib ends (172), the analyses will be of little interest except in their present use. The beef used at the boarding club at a given meal was of such a varied character—often representing four or five cuts—that it was impossible with the time at our disposal to take specimens of each particular cut for analysis. Specimens 120-123, 124 and 125 are therefore samples of miscellaneous cuts of the forequarter—rib, chuck, neck,

brisket, plate, etc., in whatever proportion the several cuts were purchased in the market for each meal.

Pork.—No. 2088 was a so-called "country-cured" shoulder. Farmers salt shoulders and hams for winter and spring use, but do not smoke them. Pork cured in this way is used largely in the country, and a considerable quantity of it finds its way into town groceries.

Poultry.-No. 2706 was a fowl of average fatness.

Dairy products.—Nos. 11, 12, and 13 are milk from a Holstein-Friesian herd and No. 14 is from a Jersey herd. No. 15 is a fair specimen of farmer's butter. Nos. 4030 and 4041 are "cottolene" and "oleomargarine," respectively.

Bread, etc.—No. 5430 is wheat bread, baker's 5-cent loaf. No. 5438 is graham bread, baker's 5-cent loaf. No. 5450 is soda and sour milk or baking powder biscuit, homemade. This is the form of wheat bread principally used in country districts, and also to a considerable extent by town population. (See Table 1.) No. 5150 is wheat flour, so-called "half patent," milled in Columbia. No. 6107 is sorghum molasses.

DIETARY STUDIES OF THE COLLEGE CLUB IN MISSOURI.

FIRST DIETARY STUDY OF THE COLLEGE CLUB (No. 94).

The study began May 10, 1895, and continued six days.

The club was composed of 98 male students, the matron, and the household servants.

The number of meals taken was as follows:

	Meals.
Men	1, 753
Women (124 meals × 0.8 meal of man) equivalent to	99
Children (20 meals × 0.7 meal of man) equivalent to	14

Remarks.—With exception of the waste no analyses were made especially for this test. When possible the estimates of composition were based upon analyses made for the final test; in other cases the averages of American analyses* were taken.

Table 6.—Composition and amounts of food materials and table and kitchen wastes in dietary of the college club in Missouri (dietary No. 94).

SECOND DIETARY STUDY OF THE COLLEGE CLUB (No. 95).

The study began May 20, 1895, and continued seven days.

During this period the club was composed of 95 male students, the matron, and household servants.

The number of meals taken was as follows:

Men	Meals, 1, 978
Women (156 meals × 0.8 meal of man) equivalent to	
Children (40 meals × 0.7 meal of man) equivalent to	. 28

Equivalent to one man seven hundred and ten days.

A considerable number of food materials were analyzed in this dietary, as was also the refuse. Such analyses are designated in the table following on page 17 by the letter a.

Table 9.—Composition and amounts of food materials and table and kitchen wastes in dietary of the college club in Missouri (dietary No. 95).

COMMENTS ON THE FOOD INVESTIGATIONS AT THE UNIVERSITY OF MISSOURI.

By W. O. ATWATER and CHAS. D. WOODS.

After Professor Gibson had presented the foregoing, as a preliminary report of the food investigations undertaken by himself and associates at the University of Missouri, and before he had opportunity to give it the final revision which had been contemplated, he was stricken with an illness which proved fatal. His greatly lamented death not only prevents the contemplated elaboration of the results already obtained, but interrupts for the time the inquiries into the food economy of the people of Missouri which had been so successfully begun at the university. Much that Professor Gibson hoped to say and do must herefore be left unsaid and undone until the work can be taken up by others. Meanwhile the writers, with whom Professor Gibson had been associated for a number of years before going to Missouri and who have been familiar with his work there, add here a few comments.

THE BREAD AND MEAT CONSUMPTION OF FAMILIES IN MISSOURI.

The method of inquiry and the results detailed on pages 7,8 are of no little interest. Of course, statistics obtained by this method are always incomplete, but with the limited time and funds at Professor Gibson's disposal it is not easy to see how better answers to the questions as to the kinds and the relative amounts of meats and bread used in the ordinary households could have been obtained, and the number of families represented in the report is so large as to give decided value to the average figures.

It is to be remembered that these statistics are from families of the classes whose sons were at the university. It would seem, therefore, that they could hardly be assumed to represent exactly the eating habits of the average people of either the country districts or the cities of Missouri.

It will be observed that the term "bread" includes (1) ordinary wheat bread raised by use of yeast and designated as "raised" bread; (2) "biscuit" made from wheat flour but not fermented, and (3) "corn bread" made from maize.

The figures of the last column of the table, "Other meats, etc.," include game and fish. The figures show the proportion which each kind makes of the total amount consumed, but give no indication of the absolute quantities per person or per family for a given time.

How largely the sources of supply regulate the character of the food consumption is illustrated by the following table, taken from the figures given on page 8:

Table 12.—Kinds of bread and meat eaten by families in country and city.

	Ki	nds of bre	ad.	Kinds of meat.		
	Raised.	Biscuit.	Corn.	Beef, veal, mutton.	Pork.	Other meats, etc.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Farmers living in country, with limited access to markets	31	54	16	24	57	19
Families living in cities or larger towns, with better markets	40	48	12	53	27	20

Evidently there is relatively much less of raised bread and more of corn bread and biscuit eaten in the country than in the town. It would seem natural to assume that the larger proportion of yeast-raised bread in the cities is due to bakers, to the ease with which good quick-acting yeast can be obtained, and to the fact that city people have more convenient markets to buy in and more ready money. The effect of supply upon the kinds of meat eaten is even more evident. Pork is easily raised on the farm, and in the form of salt pork, bacon, and ham is readily preserved for later use. On the other hand, city people can always have fresh beef, yeal, and mutton from the markets. That this accounts largely for the fact that pork constitutes 57 per cent of the meat supply of the farmers' families and only 27 per cent of that of families living in the large towns is hardly to be doubted, though, of course, the relative cost may be a factor also. The fact that beef, veal, and mutton make more than half of the total meats eaten by well-to-do people in the cities and less than a quarter of that used by thrifty farmers is naturally explained in the same way.

COMPARISON OF DIETARIES OF COLLEGE STUDENTS IN MISSOURI, TENNESSEE AND CONNECTICUT.

It will be interesting to compare the results of the studies of the two dietaries of the students' club at the University of Missouri with those of investigations of other college clubs. The only other studies of this character made in the United States, and at present available and exactly comparable with these, so far as we are aware, are several series of dietary studies of students' clubs at Wesleyan University,' Middletown, Conn., and at the University of Tennessee, Knoxville, Tenn.

¹Connecticut Storrs Station Reports, 1891-1894, and U. S. Dept. Agr., Office of Experiment Stations Bul. 21.

²U. S. Dept. Agr., Office of Experiment Stations Bul. 29.

The students of the University of Missouri were mostly residents of that State, and it would seem fair to assume that their eating habits would be more or less such as they had acquired at home, although the diet in Columbia would be somewhat modified by the markets in that eity at the time when the dietaries were made.

In the following table the results of the dietary studies at the three colleges are summarized. There is also appended to the table for comparison a suggested dietary standard for a man at light work. These comparisons are based upon the quantities of food actually eaten and not upon the total food purchased.

Table 13.—Comparison of nutrients in food eaten by college clubs in Missouri, Tennessee, and Connecticut.

nantities	

Kind of food material.	Protein.	Fats.	Carbohy- drates.	Fuel values.	Nutritive ratio.
FOOD EATEN. In Missouri: Animal Vegetable	Grams. 57 39	Grams. 156 4	Grams. 25 385		
Total	. 96	160	410	3,560	1:8.0
In Tennessee: Animal Vegetable	43 49	114 , 13	12 467		
Total	92	127	479	3, 520	1:8.3
In Connecticut: Animal Vegetable		131 8	21 315		
Total	99	139	336	3, 140	1:6.7
Average of above: Animal Vegetable	53 42	131	19 400		
Total	95	140	419	3, 420	1: 7.8
work (Atwater)	112			3,000	1: 5.5

We are far from urging that these results portray accurately the dietary practices of the people of the different sections represented by the young men in the three institutions. Still the families represented were doubtless numerous enough to represent fairly well the people of their classes and communities.

The case was similar with the club at Knoxville, whose members were nearly all from Tennessee. The homes of the students at Middletown were scattered through the northern Atlantic States, though a few were from other States and countries. The larger number were from towns with markets in which the available food materials were very similar to those in Middletown. The cost of board, like the general living expenses of the students at Middletown, was decidedly larger than that of the young men at Knoxville and Columbia.

U. S. Dept. Agr., Office of Experiment Stations Bul. 21.

It will be noticed that, as measured by the suggested standard, the food eaten in all three of the college clubs was deficient in protein and had an excess of the nutrients (fats and carbohydrates) which serve simply as fuel and tend to make the nutritive ratios wide. The standard represents nothing more than the attempt to state in a general way the proportions of nutrients which physiological experiment on the one hand and observations of the dietary habits of the best fed people on the other imply to be most appropriate. Among different dietaries here summarized the narrowest nutritive ratio is found in those representing the people who were most favorably situated with respect to both the kinds of food materials at their disposal and the pecuniary ability to select at will. The inference is that the diet of all, and especially of those in the more Southern States, would be improved by diminishing the carbohydrates and fats and increasing the protein.\footnote{1}

¹See reference to the same subject in discussion of the dietaries of the students at the University of Tennessee, U. S. Dept. Agr., Office of Experiment Stations Bul. 29.
